Project Report: Multi-Parametric Predictive Maintenance & Failure Risk Analysis

Project Title: Predictive Maintenance using Linear Regression

Date: March 2026

Name: Aman Nawaz

---

1. Executive Summary & Problem Statement

- **The Problem:** In industrial manufacturing, "Reactive Maintenance" (repairing machines only after they fail) leads to significant financial losses, unscheduled downtime, and safety hazards.
- **The Goal:** This project aims to build an analytical tool that monitors sensor data and predicts the probability of failure before it occurs, allowing for "Proactive Maintenance".

2. Technical Concepts & AI Foundations

This project applies several core Data Science and AI foundations:

- **Intelligent Agents:** The system acts as a diagnostic agent that perceives its environment through sensors (Temperature, Torque) and provides a risk-based output.
- **Statistical Foundations:** Statistical distributions were used to analyze sensor noise and identify trends in data degradation.
- **Supervised Learning:** A **Linear Regression** model was implemented to map continuous sensor inputs to a failure risk score.
- **Feature Engineering:** High-dimensional data from multiple sensors was analyzed to determine which mechanical factors (like Tool Wear) most significantly impact machine health.

3. Methodology & Implementation

- **Data Acquisition:** Utilized the **AI4I 2020 Predictive Maintenance Dataset**, containing 10,000 records of industrial sensor data.
- **Exploratory Data Analysis (EDA):** Created scatter plots and histograms to identify correlations between high process temperatures and mechanical failures.
- **Data Preprocessing:** Cleaned the dataset by removing non-numeric identifiers and splitting the data into a **Training Set (80%)** and a **Test Set (20%)**.
- **Model Training:** Developed a Regression model to find the mathematical relationship between sensor readings and the likelihood of failure.
- **Inference Implementation:** Developed an **Interactive Prediction Feature** that allows for real-time manual data entry for instant risk assessment.

4. Key Engineering Decisions

- **Regression vs. Classification:** I chose to use **Regression** because it provides a "Risk Percentage" (0-100%) rather than a simple "Yes/No".
- **Resource Prioritization:** This approach allows maintenance teams to prioritize machines with 90% risk over those with 50% risk.
- **Primary Feature Selection:** I prioritized **Torque** and **Tool Wear** as the primary indicators, as these variables showed the strongest statistical correlation with mechanical failure during the testing phase.

5. Challenges Faced & Problem Solving

- **Imbalanced Data:** In real-world industrial settings, failures are much rarer than healthy states; I had to ensure the model could accurately flag these rare events without producing excessive false alarms.
- **Feature Scaling:** Managing variables with vastly different ranges (e.g., Rotational Speed in thousands vs. Torque in tens) required careful data handling to ensure all features contributed appropriately to the prediction.
- **Extrapolation Logic:** During interactive testing, I identified that Linear Regression can produce negative percentages for extreme inputs. I implemented **Output Clamping**

(keeping values between 0% and 100%) and **Input Validation** to ensure the model remains logically sound.

6. Key Learnings

This project provided hands-on experience in the complete Machine Learning lifecycle:

- **Data to Intelligence:** Moving from raw sensor data to actionable business intelligence.
- **Environmental Interaction:** Understanding how environmental factors (Temperature) and mechanical stress (Torque) interact to affect equipment longevity.
- **Human-Centric AI:** Designing an interactive interface to make complex AI predictions accessible to non-technical users.

---

7. Conclusion

The developed system demonstrates that predictive modeling can significantly improve industrial safety and efficiency. By transitioning from reactive to proactive maintenance, facilities can minimize downtime and maximize the lifespan of expensive assets. This project successfully proves that even fundamental machine learning algorithms like Linear Regression can provide high-value diagnostic insights when paired with proper feature engineering and real-time inference capabilities.

---

8. Future Scope

To transition this project from a prototype to a production-ready industrial tool, the following enhancements are planned:

- **Advanced Algorithmic Modeling:** Moving toward **Deep Learning** or **Anomaly Detection** algorithms to identify even subtler patterns of machine degradation before they lead to failure.

- **Non-Linear Complexity:** Implementing **Random Forest** or **XGBoost** to better handle complex, non-linear relationships that Linear Regression may oversimplify.
- **Explainable AI (XAI):** Integrating tools like **SHAP** to explain "why" the model predicted a certain risk, providing transparency for factory operators.
- **Hardware Integration:** Deploying the model on **Edge Computing** devices (like a Raspberry Pi) to process live sensor data directly from the machinery.
